

Build the stage layer

Take-Home Exercise: Complete before the live session.

For Part 1, you'll find two JSON files attached to the email. These represent a snippet of raw data as it lands in our data flow — think of them as two parallel raw sources feeding the same pipeline.

Goal: Design and build a pipeline to ingest two parallel raw JSON sources into a consolidated staging layer.

- **Staging Schema:** Define table structure, field names/types, and your strategy to reconcile sources into a unified layout.
- **Transformation Logic:** Write the code (SQL, Python, dbt, etc.) transforming raw JSON to staging output.

Deliverables:

1. Return your code/model along with the staged dataset export.
2. Write about how we could implement this pipeline in a production environment.

Note: We value your reasoning and trade-off analysis over finding a single "correct" answer. Please document any assumptions made regarding ambiguous data.

Live Session: Live session with an engineer building directly on your output.
